Disclaimer and Limited Warranty
Sonex Aircraft, LLC, makes every effort to assure that each AeroInjector meets high quality and durability standards, and warrants to the original purchaser that this product is free of defects in material and workmanship for the period of one year from the date of purchase. This warranty does not apply to damage due directly or indirectly to misuse, abuse, negligence or accidents, repairs or alteration out side our facilities or lack of maintenance. Due to the experimental nature of the AeroInjector, the end user is solely responsible for determining AeroInjector's suitability, installation and use. Sonex Aircraft, LLC, will in no event be liable for death, injuries to person or property, or incidental, contingent, special, or consequential damages arising from use of our product.

Important:
By opening the package you agree to accept all responsibility for the use of this product and accept all such printed terms.

EXPERIMENTAL USE ONLY
Not TSO'd for Certified Aircraft

This guide was written to help you achieve a dependable installation and outstanding performance from your AeroConversions AeroInjector. Properly installed and tuned, the AeroInjector has gained a reputation for increasing power and reducing fuel consumption on a broad range of aircraft and auto-conversion engines.

AeroConversions
A Product Line of Sonex Aircraft, LLC.

Overview of Features
The AeroInjector is precision machined from solid 6061 aluminum billets and premium Delrin. There are only two moving parts: a fuel/air "throttle slide" that moves with the cockpit throttle control and meters combustion air and fuel, and a tapered needle that moves with the cockpit mixture control to control in-flight mixture adjustments and serve as an idle cut-off valve.

The throttle slide carries within it an infinitely adjustable tapered fuel needle. Three (3) different needles are included with each AeroInjector, and others are available. Spigot or flange mounts easily adapt the AeroInjector to popular aircraft and auto engine conversions. A clamp for the mixture cable is built in to the body of the AeroInjector, and the throttle cable is attached directly to the throttle slide. The AeroInjector’s intake design accepts air filters or carb heat ducts.

The AeroInjector works in up-draft, side-draft, and down-draft configurations. Gravity feed is recommended where possible. If a fuel pump is required, a fuel pressure regulator must also be used. By design, the AeroInjector is extremely resistant to icing.

Combined, these features make the AeroInjector one of the most versatile and adaptable injectors ever developed.

AeroInjector Size Recommendations
The following chart is a general guideline to injector sizing for a variety of popular engines. Please call for recommendations for your particular engine.

Weights:
AeroInjector* .......... 1 lb. 4 oz.
Air Filter (optional) ...... 11.6 oz.

*Average weight - actual weight varies slightly by mount size and style.

Specifications subject to change without notice.
**Fuel Delivery Systems**  
Most fuel systems can be made to work with the AeroInjector's floatless design. If you have a system not represented on this page, please call for advice.

**IMPORTANT:** The fuel system must be able to deliver 1.5 times the engine's required fuel flow at full throttle.

**Gravity Feed System**  
A gravity feed system is by far the safest and most reliable. The AeroInjector requires very little head pressure to operate effectively. For this system to be effective, the fuel tank outlet must be higher than all the other components of the fuel delivery system in a tail low (climb) configuration or fuel flow may be disrupted.

![The gravity feed system.](image1)

**Fuel Pump and Regulator System**  
If your aircraft requires a fuel pump (i.e.: for wing tanks or pusher engines) a fuel pressure regulator must also be installed to limit fuel pressure to about 1 to 2 psi. A Holley Standard Pressure Regulator (1-4 psi range, or equal), has been found to be effective for these installations.

![The fuel pump / regulator system.](image2)

**Return Line System**  
In a fuel return system a fuel line “T” is installed between the regulator and the AeroInjector with a return line to the tank. This will supply fuel to the AeroInjector without excessive pressure. Excess fuel returns to the tank.

![The return line system.](image3)

**Header Tank System**  
Pumping fuel from the main tank(s) to a small header tank mounted above the injector will provide gravity feed to the AeroInjector. A return line from the header to the main tank(s) is required so excess fuel can return to the main tank without a build-up of pressure. This type of system assures some reserve fuel in the event the fuel pump fails, and eliminates the need for a fuel regulator.

Mounting the AeroInjector
The ideal mounting position for an AeroInjector is in the updraft configuration, as low as possible, to assure constant gravity fuel flow even in extreme nose high attitudes. However, the AeroInjector functions well in any position.

WARNING: Fire hazard. Do not install the AeroInjector where dripping fuel can contact hot exhaust or electrical equipment. If necessary, install a drip pan to catch/deflect dripping fuel. Always close the mixture shut-off valve and fuel valve when the engine is off.

IMPORTANT: If the cockpit mixture control is not pulled to the Idle/Cut-off position when the engine is off, fuel will continue to flow through the AeroInjector. This may fill the AeroInjector/intake causing engine flooding or spill-over, which is a fire hazard.

Note: If you are using an optional AeroConversions Air Filter or Intake Flange Adapter it is easier to install these before mounting the AeroInjector to the intake manifold. See page 15.

Spigot Mounted AeroInjector
The outside diameter of the AeroInjector’s spigot must match the inside diameter of the engine’s hose mount.

If you are replacing a carburetor, the existing hose mount can mostly likely be reused after inspection. Replace the hose if it shows signs of deterioration.

If you do not have a hose, we recommend fuel tank filler hose (or equivalent fuel proof hose) of the proper diameter. Do not use radiator hose.

Attach the hose and AeroInjector to the engine with two stainless steel hose clamps. Updraft and sidedraft installations must be further secured with safety wire to the intake manifold, as shown in the photo, next column.

Flange Mounted AeroInjector
A flange mounted AeroInjector will bolt directly to a four-hole Continental or Lycoming intake manifold. Use a standard gasket or a small amount of gasket-maker when mating the AeroInjector to the manifold.

To mount a standard four-hole flange to a two-hole manifold, fabricate an adapter plate from 1/4" to 3/8" thick 6061-T6 aluminum flat stock. Use standard gaskets or a small amount of gasket-maker on both sides of the adapter when mating the AeroInjector to the manifold.

This sample adapter plate has 4 holes matched to the AeroInjector’s flange, and two matched to the 2-hole intake manifold. The center hole matches the inside diameter of the intake bell.
Throttle Installations Acceptable for Use with the AeroInjector

The AeroInjector's design requires the use of a reversing throttle quadrant or reversing bellcrank for proper operation of the throttle slide. Either of these convert the standard "push to accelerate" cockpit throttle motion into the AeroInjector's required "pull to accelerate" cable motion. As such, "push/pull" throttle cables which do not reverse the throttle cable's motion must not be attached directly with the AeroInjector.

Reversing Throttle Quadrants

A reversing throttle quadrant is the preferred installation for the AeroInjector as it provides the proper cockpit control and cable motion while eliminating the need for an intermediate reversing bellcrank. The AeroConversion Throttle Quadrants are the ideal match for the AeroInjector.

Push / Pull and Vernier Throttle Cables

DANGER. DO NOT connect a push/pull or vernier throttle cable directly to the AeroInjector as this will result in a non-standard control installation where pulling the cockpit throttle control will result in the application of full throttle. The installation of a push/pull or vernier throttle cable requires a reversing bellcrank between the cockpit throttle control and the AeroInjector to convert the pushing action of the cockpit throttle control into the pulling action the AeroInjector requires to open the throttle.

The common push/pull throttle cables, as shown here, can not be connected directly to the AeroInjector. To use this type of throttle cable a reversing bellcrank must be installed between the throttle cable and the AeroInjector.
Cables Ends Suitable for Use with the AeroInjector

Three types of cable ends, all shown below, can be attached to the AeroInjector.

Cable end types which can be used with the AeroInjector, from top to bottom:
- Solid wire (bent 90°).
- Flexible cable with integral barrel end.
- Flexible cable with integral ball end (requires ball adapter, shown).

Specific installation instructions for each type of cable begin on page 8.

Ball End Cables - Recommended Installation

Ball end cables must have an integral ball end which measures .1875” to .192” diameter. The cable must be galvanized or stainless steel and minimum 1/16” diameter. Ball end cables must be used with a 1/4” diameter x 1/4” long barrel adapter.

An 84” long ball end cable (part no. ACV-Q01-39) and ball adapter (part no. ACV-Q01-36) are included as standard equipment with all AeroConversions Throttle Quadrants.

Solid Wire

Solid (music) wire cables must be .062” minimum diameter and be constructed of stainless steel or high carbon wire which meets spring temper specification MIL-W-6101. After bending the end of the cable 90 degrees, inspect the cable for cracks or nicks. Reject any wire that has cracks or nicks.

Barrel End Cables

Barrel end cables must have an integral barrel end which measures 1/4” in diameter and 1/4” long. The cable must be galvanized or stainless steel and minimum 1/16” diameter.

Note: For detailed installation of a barrel end cable use the Ball End Cable instructions but delete the use of the barrel adapter.

Cable Routing

The throttle cable must be routed so it does not have any sharp bends. A grommet must be used where the throttle cable passes through the firewall.

CAUTION: Do not allow the throttle cable to come in contact with the battery terminals.

CAUTION: Do not allow the throttle cable to come in contact with the exhaust.
Solid Wire Throttle Cables

The throttle cable must be installed in the AeroInjector prior to connecting it to the Throttle Quadrant.

Important: The wire diameter must be .065" to .075" minimum.

1. Disassemble the AeroInjector by removing the 6 machine screws which hold the body together. You will need a 9/64" hex wrench and a 7/32" open end wrench.

2. Remove the mixture needle assembly. See "Changing the Mixture Needle" in the "Tuning Procedures" section of the AeroInjector manual.

3. Pass the solid wire throttle cable through the cable adjuster and bend the end 3/8" of the wire 90 degrees.

4. Install the wire in the slide so the bent end engages the hole in the throttle slide. The throttle slide needs to be removed from the AeroInjector body to do this.

5. With the wire engaged in the throttle slide and the throttle slide back in the body of the AeroInjector, install the mixture needle assembly. Make sure the flat side of the needle faces towards the intake manifold. See "Changing the Mixture Needle" in the "Tuning Procedures" section of the AeroInjector manual.

6. Make sure the inside of the AeroInjector body is free of debris and re-assemble the AeroInjector. Check for free movement of the throttle slide.

7. Attach the AeroInjector to the intake manifold.

8. The throttle cable must be routed so it does not have any sharp bends. A grommet must be used where the throttle cable passes through the firewall.

CAUTION: Do not allow the throttle cable to come in contact with the battery terminals.

CAUTION: Do not allow the throttle cable to come in contact with the exhaust pipes.

The cable housing must be long enough to be inserted in the cable adjuster on the AeroInjector and on the throttle quadrant.

After determining the best cable routing, trim the housing to length. Do not trim the wire. The housing should be removed from the wire to avoid cutting the wire.

9. Strip 3/8" of the black casing off each end of the cable housing, exposing the metal core.

10. Push the exposed metal core into the cable adjuster and secure it with the included set screw (ACV-Q01-23). Do not over-tighten or you may pinch and bind the cable.
11. Insert the throttle cable wire between the washers and through the hole in the throttle cable clamp of the throttle quadrant but do not tighten it.

12. Push the exposed metal core of the throttle cable into the cable adjuster on the throttle quadrant and secure it with the included set screw (ACV-Q01-23). Do not over-tighten or you may pinch and bind the cable.

13. Push the throttle lever to the "full throttle" position.

14. Make sure the throttle slide of the AeroInjector is fully open (full throttle position).

15. Tighten the nut which secures the throttle cable wire in the throttle cable clamp.

16. Operate the cockpit throttle control through it's full range of movement and make sure the throttle slide is opening completely as well as closing against the idle stop screw.

17. Trim the exposed throttle wire, leaving 1/4" to 3/8" extending beyond the washers.
Flexible Throttle Cable - Ball End with Adapter

This installation requires a 1x19 flexible cable with a 1/16" diameter cast ball end and a ball adapter. Both of these parts are available from Sonex Aircraft and are identified by part number in the photo, right.

1. Disassemble the AeroInjector by removing the 6 machine screws which hold the body together. You will need a 9/64" hex wrench and a 7/32" open end wrench.
2. Remove the cable from the cable housing.
3. Pass the cable through the ball adapter and cable adjuster and then place it in the recess in the throttle slide.
4. Make sure the inside of the AeroInjector body is free of debris and re-assemble the AeroInjector. Check for free movement of the throttle slide.
5. Attach the AeroInjector to the intake manifold.
6. Route the throttle cable so it does not have any sharp bends. A grommet must be used where the throttle cable passes through the firewall.

CAUTION: Do not allow the throttle cable to come in contact with the battery terminals.

CAUTION: Do not allow the throttle cable to come in contact with the exhaust pipes.

The cable housing must be long enough to be inserted in the cable adjuster on the AeroInjector and the cable adjuster on the throttle quadrant.

After determining the best cable routing, trim the housing to length. Do not trim the cable.

7. Strip 3/8" of the black casing off each end of the cable housing, exposing the metal core.

8. Push the exposed metal core into the cable adjuster and tighten the set screw to secure the housing.

9. Insert the flexible cable between the washers and through the hole in the throttle cable clamp but do not tighten the locking nut.

Right: Insert the exposed metal core into the cable adjuster and tighten the set screw to secure the housing.

Set Screw

9, 13, 15

These photos show how easily the ball-end cable and ball adapter are to install.
10. Push the cable housing into the cable adjuster on the throttle quadrant and secure it with the included set screw. Do not over-tighten the set screw or you may pinch and bind the cable.

11. Push the throttle quadrant lever to the "full throttle" position.

12. Make sure the slide of the AeroInjector is fully open (full throttle position).

13. Tighten the locking nut which secures the throttle cable wire in the throttle cable clamp.

14. Operate the cockpit throttle control through its full range of movement and make sure the throttle slide is opening completely as well as closing against the idle stop screw. Adjust the cable length as needed to provide the full range of throttle movement.

15. Trim the exposed throttle cable, leaving 1/4" to 3/8" extending beyond the washers.
**INSTALLATION**

**Install the Mixture Cable**
The mixture cable must be a push-pull bowden wire style cable.

**Cable Routing**
The mixture cable must be routed so it does not have any sharp bends. A grommet must be used where the mixture cable passes through the firewall.

**CAUTION:** Do not allow the mixture cable to come in contact with the battery terminals.

**CAUTION:** Do not allow the mixture cable to come in contact with the exhaust pipes.

**Connecting the Mixture Cable**
1. If necessary, up-drill the hole for the mixture cable clamp to fit your cable. **Do not over-size the hole.**

2. Insert the mixture cable housing in the mounting hole. **Do not tighten the clamping screw at this time.**

3. Pass the mixture cable through the swivel nut in the mixture arm. **Do not tighten the swivel nut at this time.**

4. Push the cockpit mixture control knob all the way in (full rich).

5. Rotate the mixture arm 45° from perpendicular to the AeroInjector body, as shown in the following photo.

6. Slide the mixture cable housing through the mounting hole until there is 2" of wire exposed between the mixture arm and the end of the mixture cable housing (see photo). Make sure the mixture arm is still in position (step 5) and the cockpit mixture control knob is still pushed all the way in ("Full Rich").

7. Secure the mixture cable in the mixture cable clamp with the set screw. **Do not over-tighten the set screw.** The set screw should firmly grip the mixture cable housing, but not bind the movement of the wire.

8. Tighten the screw of the swivel nut against the wire. **Do not over-tighten the screw.** The set screw should firmly grip the mixture cable but still allow the swivel freedom to turn as the mixture arm is operated.

9. Operate the mixture knob several times. The mixture should operate smoothly. If it does not, make sure the mixture cable set screw has not been over-tightened (step 7), the swivel nut has not been over-tightened, and the cable routing is free of sharp bends.

**A passage through the injector’s body and a set screw (arrow) secure the mixture cable to the AeroInjector.**

**Pass the mixture cable through the swivel nut as shown.**
10. Pull the mixture cable out until it stops ("Idle Cut-Off"). The mixture control arm must be in the "closed" position with some wire still exposed beyond the cable housing. If there is no wire visible (bottom photo), the mixture arm may not be fully closed.

When the cockpit mixture control knob is pulled all the way out (Idle Cut-off), there must still be some wire exposed between the cable housing and the mixture lever (see arrow). If there isn't, contact with the cable housing may keep the mixture arm from closing fully.

11. Push the cockpit mixture control all the way in ("Full Rich"). The mixture arm must be at least 45° from perpendicular to the AeroInjector body, as shown in step 5.

**Note:** The position of the mixture arm on the fuel valve can be adjusted if needed.

a. Loosen the swivel nut and remove the mixture cable.

b. Turn the mixture arm clockwise until the fuel valve is seated in the off position.

c. Loosen the screw which locks the mixture arm on the fuel valve.

d. Rotate the mixture arm on the fuel shaft to the desired position. This will be the new "Idle Cut-off" position of the mixture arm.

e. Tighten the screw to lock the mixture arm in place.

f. Reconnect the mixture cable.

g. Make sure the cockpit mixture control still provides enough movement of the mixture arm to open the valve from "Idle Cut-off" to "Full Rich".

A screw locks the mixture arm in place on the fuel valve. Loosening the screw allows the position of the mixture arm in relation to the valve to be adjusted.
Install the Fuel Line
Use "AN" aircraft grade fuel lines and fittings to connect the AeroInjector to your fuel system. The use of barbed fittings and hose clamps in the fuel system is strongly discouraged.

AeroConversion recommends a 3/8" diameter fuel line (-06 hose).

The body of the AeroInjector is tapped to accept 1/8 NPT fittings. Apply teflon paste (do not use teflon tape) to the threads before installation.

Intake Air, Air Filter, and Carburetor Heat Installation
The intake bell of the AeroInjector is designed to accept 2-1/4" SCAT tubing. It may also be fitted directly with the optional AeroConversions air filter assembly (see next page).

Carburetor Heat
The design of the AeroInjector makes it resistant to icing typically associated with carburetors that have venturis and butterfly valves. While each owner must make their own decision on installing and using carburetor heat - and some countries require it - we do not recommend it's use.

Intake Air and Air Filtering
The AeroInjector must be allowed to draw combustion air freely - it is not designed for use with ram air. Ram air will cause the mixture to become lean as speed increases.

Intake air can be drawn through a remotely mounted carb heat/air filter box, or the optional AeroConversions air filter. Installation of the optional AeroConversions air filter is described on the next page.
Installing the Optional AeroConversions Air Filter or Intake Flange Adapter

The optional AeroConversions air filter or intake flange adapter are mounted directly to the intake bell of the AeroInjector.

IMPORTANT: While drilling and tapping the intake bell use care to keep debris from entering the AeroInjector.

1. Slide the air filter or intake flange adapter onto the intake bell as far as it will go.

Note: Only one bolt is needed to secure the air filter to the AeroInjector. At least two bolts must be used to mount the intake flange adapter.

2. Insert a 3/16" diameter drill bit through any of the mounting holes in the air filter or intake flange adapter and twist it a few times to mark the AeroInjector's intake bell.

3. Remove the air filter or intake flange adapter and carefully drill a 1/8" diameter pilot hole squarely through the intake bell at the mark.

4. Up-drill the hole with a #21 drill.

5. Tap the hole with a 10-32 tap and cutting fluid.

6. Slide the air filter in place, apply Locktite 242 to the threads of the AN3 bolt, and install the bolt and AN960-10 washer.

Note: If the bolt does not smoothly engage the threaded hole it is acceptable to enlarge the hole in the air cleaner or intake flange adapter to provide a degree of play.
How the AeroInjector Works
The Fuel Mixture Needle and Throttle Slide move as one unit when the cockpit throttle control is operated. The position of the mixture needle relative to the throttle slide determines the fuel/air ratio. The tuning process establishes the optimum fuel/air ratio for the full range of throttle travel.

Fuel Metering
Fuel enters the AeroInjector at the Mixture Control Valve, which is cockpit controllable with a mixture control cable. The valve controls the volume of fuel available to the engine: from none (cockpit mixture control set to "Full Lean" or "Idle Cut-off"), to maximum (cockpit mixture control set to "Full Rich"). Like any other carburetor with a cockpit mixture control, the mixture is normally set to "Full Rich" for start-up, climb, and landing, yet provides mixture control (leaning) for optimum performance and fuel efficiency while cruising.

Note: A more lean no. 1 needle (part no. ACV-C10-11) and more rich no. 4 needle (part no. ACV-C10-14) are available options.

Air Metering
Combustion air is metered by the Throttle Slide. The throttle slide moves when the cockpit throttle control is operated, altering the opening of the air passage.
For most installations the throttle slide should be allowed to open all the way. However, some installations may encounter rough engine operation or "balking" near full throttle. If this occurs - a characteristic of "over-carburation" - note the position of the throttle slide just before the engine balks and adjust the throttle linkage to prevent the throttle slide from opening further. See page 19.

### Idle Speed
The idle speed is set by the position of the idle speed stop screw. This screw, located near the fuel inlet, limits how far the throttle slide can close, assuring the engine has an adequate supply of air to run when the cockpit throttle control is fully retarded.

**IMPORTANT:** Read and become familiar with the entire Tuning Procedure before tuning your AeroInjector. This section does not describe how to tune the AeroInjector, rather, how to make the individual mixture and idle adjustments which will be necessary during the tuning process.

#### Mixture and Idle Adjustments

**Mixture Needle**
The mixture needle is mounted in a needle carrier which is installed in the throttle slide. The needle carrier has an adjustment screw which allows infinite adjustment of the mixture needle.

**Idle Speed Stop Screw**
The idle speed stop screw limits how far the throttle can close. The idle screw is locked in position by a locknut which is tightened against the body of the AeroInjector after the idle speed has been set.

**Dust Cap**
Remove the dust cap to gain access to the Needle Adjustment Screw.

**Needle Carrier and Adjustment Screw.**

While it is seldom necessary to remove the needle carrier during tuning, this photo shows the needle carrier which is installed in the throttle slide. The AeroInjector is shipped with three different needles, no. 2, no. 2.5, and no. 3.

**To adjust the Mixture Needle:**
1. Lock the throttle in the "Full Throttle" position.
2. Remove the dust cap.
3. A set screw locks the needle carrier in place. Remove the set screw with a 3/16" ball end hex wrench.

4. Adjust the mixture needle with a 3/16" ball end hex wrench. Adjust the needle in 1/8 to 1/2 (maximum) turn increments.

   To richen the mixture, turn the wrench counter-clockwise.
   To lean the mixture, turn the wrench clockwise.

5. Re-install the set screw so it is snug against the needle carrier.

   IMPORTANT: Always re-install the set screw after an adjustment has been made. Running the engine without the set screw in place can allow the position of the mixture needle to change.

6. Re-install the dust cap.

### Changing the Mixture Needle

The AeroInjector is supplied with three different mixture needles, each offering a richer or leaner fuel ratio across the entire throttle range. Each needle is stamped with a number on its flat taper: 2, 2.5, or 3. Needle 2 provides the leanest mixture, and 3 the richest. The number 2 needle is factory installed and is the correct needle for most applications.

Note: Other needle profiles (no. 1, more lean, and no. 4, more rich) are available. Please contact AeroConversions to discuss your needs if the standard needles do not provide proper results.

A needle should only be replaced after tuning efforts have shown the installed needle is too rich or too lean across the entire throttle range, as described in "Tuning the AeroInjector".

**To Replace a Mixture Needle:**

1. Lock the throttle in the "Full Throttle" position.
2. Remove the dust cap.
3. Remove the needle locking set screw with a 3/16" ball end hex wrench.
4. Remove the needle carrier from the throttle slide with a 3/16" ball end hex wrench turned counter-clockwise.
5. Loosen the set screw which locks the mixture needle in the needle carrier with a 1/16" hex wrench and remove the needle.
6. Install a needle with a richer or leaner profile, as needed. Make sure the notch in the needle lines up with the set screw in the needle carrier and re-install the set screw.
7. Use a fine point marker to mark the beginning of the needle's taper. Make sure the mark encircles the entire needle.
8. Re-install the needle carrier in the throttle slide. Make sure the flat, tapered side of the needle faces the engine side of the AeroInjector. Screw the carrier into the throttle slide until the marker line on the needle is visible at the edge of the throttle slide.

9. Re-install the set screw so it is snug against the needle carrier.

IMPORTANT: Always re-install the set screw after an adjustment has been made. Running the engine without the set screw in place can allow the position of the mixture needle to change.

10. Re-install the cap.

Adjusting the Idle Speed Stop Screw

The Idle Speed Stop Screw controls the idle speed by limiting how far the throttle slide can close. If the slide closes too far, fuel and air will be restricted and the engine will stop. If the slide does not close enough, the engine will idle too high. The idle speed stop screw is adjusted with a 9/64" hex wrench. The screw is locked in place with lock nut tightened against the AeroInjector's body.

To increase the idle speed, turn the idle screw clockwise.

To decrease the idle speed, turn the idle screw counterclockwise.

Idle adjustments may be needed during initial tuning, but the final idle setting is performed after the mixture needle has been properly set and the engine is warm (oil temperature at least 100°F.) Refer to your engine specifications for the correct idle speed.

A 9/64" hex wrench is used to adjust the idle speed stop screw. The lock nut is tightened / loosened with an 11/32" open-end wrench.

Adjusting the "Full Throttle" Position of the Throttle Slide

Some installations may encounter rough engine operation or "balking" near full throttle. If this occurs, the movement of the throttle slide needs to be limited to prevent it from opening and exposing the entire intake air passage.

1. Note the position of the throttle slide just before rough operation begins.

2. Adjust the throttle cable's length/position so the throttle lever is in the full throttle position, but the throttle slide is in the position noted in step 1. This will generally require shortening the throttle cable.
When is it in Tune?
A properly tuned AeroInjector will accept throttle changes smoothly, without missing or balking, and, at full throttle, will exhibit an Exhaust Gas Temperature (EGT) increase of 90° to 100°F when the cockpit mixture control is pulled from "Full Rich" to "Peak Lean".

We define Peak Lean as the engine manufacturer's maximum recommended EGT. While this varies from engine to engine, most engines set a maximum EGT near 1400°F. Refer to your engine's operating limits.

Note: Since calibration of EGT gauges/probes is difficult, the EGT should be used to measure change in temperature rather than absolute temperature.

Peak Lean generally occurs just before the engine begins to run rough. Continuing to pull the cockpit mixture control further lean will result in higher than recommended EGTs, rough engine operation, and, eventually, fuel starvation.

What is "Rich"?
We define "rich" as a fuel/air ratio which has too much fuel.

Symptoms:
- Black, smoky exhaust.
- Engine runs with weak, intermittent firing.
- Pulling the mixture control knob towards lean will improve engine firing and reduce the amount of black exhaust.
- EGT increases more than 100°F when the cockpit mixture control is pulled back from "Full Rich" to "Peak Lean".

Action to take:
- Turn the needle adjustment clockwise in 1/8 to 1/4 turn increments and run the engine to test the new setting.
- If continued needle adjustments do not produce the desired 90° to 100°F EGT spread, install a lowered number needle. See page 18.
- If your fuel system requires a fuel pump, the pressure regulator may need to be set lower (1 to 2 psi is normal).

What is "Lean"?
We define "lean" as a fuel/air ratio which has too little fuel.

Symptoms:
- Engine will not start
- Engine runs rough and exhaust is free of black smoke.
- Engine runs rough and does not improve, or stalls, as the cockpit mixture control is pulled towards lean.
- Engine will not take throttle.

Compensating for Seasonal Changes
Some climates may require small seasonal adjustments to the mixture needle. These are generally needed once in late Fall and again in late Spring to compensate for changing air density. If your engine exhibits symptoms of running too rich as the weather warms, and too lean as the weather cools, the mixture needle may need to be adjusted no more than 1/4 to 1/2 turn richer or leaner, as appropriate.
Tuning the AeroInjector - Step by Step

**IMPORTANT:** Read and understand this entire chapter before tuning your AeroInjector. This chapter is broken into three sections: How the AeroInjector Works, Mixture and Idle Adjustments, and Tuning the AeroInjector. The first two sections contain important information you should understand before you begin to tune your AeroInjector.

**DANGER:** Avoid serious injury or death. Turn the engine off using a checklist before making any adjustments to the AeroInjector. A typical checklist is provided on page 22 of this manual, but it may need to be modified for your particular aircraft.

**DANGER:** Avoid serious injury or death. Remain clear of the propeller at all times while tuning the AeroInjector.

**DANGER:** Avoid serious injury or death. Tie down and chock the aircraft while tuning the AeroInjector.

**WARNING:** Avoid serious burns. The engine and exhaust will become hot during the tuning process.

**CAUTION:** Avoid damaging the engine. Air cooled engines are not adequately cooled during ground operations. Monitor your engine's temperatures and oil pressure, and limit ground running as much as possible.

**IMPORTANT:** Tuning should be done with a qualified helper. One person remains in the cockpit to operate the throttle and monitor the engine instruments while the other makes adjustments to the AeroInjector (only after the engine is shut down) and observes the exhaust.

### Tools Required
- 3/16" Hex Wrench
- 9/64" Hex Wrench
- Start-up checklist (see page 22.)
- Shut-down Checklist (see page 22.)

### To Tune the AeroInjector:
1. Tie-down and chock the aircraft.
2. Set the parking brake
3. Make sure the aircraft has an adequate fuel supply. The use of 100LL is strongly recommended during the tuning process to eliminate poor fuel quality as a possible source of poor engine performance and tunability.
4. Start the engine using an appropriate checklist.
   - If the engine starts and idles smoothly, even with slightly black exhaust, allow the engine's oil temperature to warm up to 100°F. Do not allow the CHT and EGT to exceed the engine manufacturer's limit. Continue to step 5.
   - If the engine does not start, or starts and runs rough, shut down the engine using an appropriate checklist and adjust the mixture needle as needed. See "When is it in Tune?" page 20. After making an adjustment, repeat this step.
5. Gradually increase the throttle to full static RPM.
   - If the engine takes full throttle well with clean exhaust, continue with step 6.
   - If the engine takes full throttle well but exhibits some black exhaust, shut down the engine using an appropriate checklist and adjust the mixture needle leaner. See "When is it in Tune?" page 20. After making an adjustment, repeat step 4.
   - If the engine runs rough, balks, or quits, shut down the engine using an appropriate checklist and adjust the mixture needle as needed. See "When is it in Tune?" page 20. After making an adjustment, repeat step 4.
   - If the engine takes throttle well but balks or runs rough only at or near full throttle, the Throttle Slide's travel needs to be limited. Shut down the engine using an appropriate checklist and adjust the Throttle Slide. See page 19. After making an adjustment, repeat step 4.
6. With the engine running at full throttle:
   a. Gradually pull the cockpit mixture control lean until the engine begins to run rough, and then richen slightly for smooth operation. Note the EGT.
   b. Advance the cockpit mixture control to full rich and note the EGT.
   c. Retard the throttle smoothly to idle and shut down the engine using an appropriate checklist
   - If the EGT spread was 90° to 100°F, and the engine responded well to the throttle through the entire range, the mixture needle is properly set. Continue with step 7.
   - If the EGT spread was greater than 90° to 100°F, the mixture is too rich. Adjust the mixture needle for a leaner mixture (see page 18).
   - If the EGT spread was less than 90° to 100°F, the mixture is too lean. Adjust the mixture needle for a richer mixture (see page 18).
   - If continued adjustment does not achieve the desired 90° to 100°F spread, try the next numbered mixture needle. See "Changing the Mixture Needle", page 19.
7. After the mixture needle is properly set, final idle adjustments can be made (see page 21).
8. Test run the engine through it's full RPM range and make sure it:
   - Responds to the throttle smoothly
   - Idles properly
   - Exhibits a 90° to 100°F EGT differential at full throttle when the cockpit mixture control is pulled from full rich to "peak lean".

*Note:* Additional tuning may be needed after initial flight testing or after a new engine has been broken in.
Starting Checklist - Electric Start
1. Brakes - Set
2. Mixture - Full Lean (Idle Cut-off)
3. Fuel Valve - On
4. Master - On
5. Mags - On
6. Throttle - Slightly Open
7. Fuel Pump - On
8. Clear Prop
9. Mixture - Full Rich

Note: With the mixture open and the fuel valve on, fuel will flow through the AeroInjector. Do not delay starting the engine.

10. Starter - Engaged

The engine will normally start with one or two turns of the propeller in warm weather and six to eight turns in cold weather. If the engine does not start immediately, pull the mixture off, turn off the fuel pump, and close the fuel valve before investigating the problem.

Starting Checklist - Hand Propping
DANGER: Do not attempt to hand prop an aircraft without proper training. Serious injury or death can occur.

WARNING: Do not hand prop an aircraft equipped with an electric starter. Remove the aircraft from service until proper repairs can be made to the electric starting system.

1. Tie down and chock the aircraft.
2. Brakes - Set
3. Mags - Off
4. Mixture - Full Lean (Idle Cut-off)
5. Fuel Valve - On
6. Throttle - Slightly Open
7. Mixture - Full Rich for a few seconds then Full Lean.
   This "primes" the engine.
8. Pull prop through 2 to 4 blades
9. Mags - On
10. Prop engine until it starts.
11. Mixture - Full Rich

If the engine does not start, repeat procedure.

Flooded Engine - Clearing
Weak, intermittent firing indicates flooding. Excess fuel can be cleared from the combustion chambers with the following procedure:

1. Mixture - Full Lean (Idle Cut-off)
2. Fuel pump - Off
3. Fuel shut off valve - Off
4. Mag switch - Off
5. Throttle - Full Open
6. Engage the starter for a few seconds.
7. Repeat the starting procedure.

Leaning for Best Performance at Cruise
Take-off, full-power climb, and landing must always be performed with the mixture set at full rich. Once level cruise has been established, however, engine performance and fuel economy will both benefit by proper leaning.

1. Establish level cruise.
2. Slowly pull the mixture control Lean until the engine begins to run a little rough.
3. Note the maximum indicated EGT (if the aircraft is equipped with an EGT).
4. Slowly push the mixture control Rich until the engine runs smooth. If your aircraft has an EGT, this will be approximately 50 degrees F. cooler than the temperature noted in step 3.

Adjusting the mixture as described above will result in maximum power (higher RPMs), as well as minimum fuel consumption for any throttle setting.

Important: Mixture adjustment must be repeated with any change in throttle setting or altitude.

5. Push the mixture control to "Full Rich" before landing.

Shut-Down Checklist
1. Mixture - Full Rich
2. Throttle - Idle
3. Fuel Pump - Off
4. Mixture - Full Lean (Idle Cut-off)
5. Ignition - Off
6. Fuel Valve - Off (Closed)
   WARNING: Fire hazard. Failure to turn off the main fuel valve may result in fuel flowing from the AeroInjector after shut-down.
7. Master switch - Off
8. Mags - Off

Note: These basic checklists may need to be altered for your particular aircraft.
The AeroInjector is an extremely simple design which can be expected to function faultlessly if properly installed and tuned. If you experience problems with your AeroInjector, please review this list of troubleshooting tips for possible causes, and the contents of this manual for proper installation/tuning/operation. Should you be unable to identify or resolve your problem, contact AeroConversions for technical assistance.

**Unable to Tune the AeroInjector**

**Fuel delivery inadequate.**
Inspect fuel system for restrictions.

Make sure the cockpit mixture control is set on "Full Rich" and the AeroInjector mixture lever is properly positioned.

Make sure the fuel tank has sufficient fuel for consistent head pressure while tuning.

**Fuel delivery excessive.**
Inspect fuel system for restrictions.

Fuel pressure set too high/low on aircraft requiring a fuel pump.

**Mixture needle improperly installed.**
"Flat" of the mixture needle not facing the proper direction. Refer to the "Tuning Procedures" section of this manual.

**Mixture needle lock screw not installed after each mixture needle adjustment, allowing the needle to move while the engine is running.**
Install the mixture needle lock screw after each mixture adjustment.

**Incorrect needle installed.**
Install a different needle per tuning instructions in this manual.

**Needle has been modified from original profile.**
Discard needle and replace with a new one from AeroConversions.

**Needle adjustments too aggressive.**
Limit needle adjustments to 1/4 turn or less.

**AeroInjector modified by installer.**
Restore AeroInjector to original configuration.

**Air intake restricted.**
Inspect air intake for restrictions, sharp bends, dirty air filters, etc.

**Ram air installed.**
Remove ram air.

**Incorrect propeller installed.**
A propeller which is too coarse or too large will limit the engine's ability to produce power. This cannot be tuned away with the AeroInjector. Install a propeller that will allow the engine to reach the engine manufacturer's minimum static RPM at wide open throttle.

**Engine requires service.**
An engine in need of maintenance will be difficult or impossible to tune. Check valve settings, cylinder compression, timing, magnetos, spark plugs and wires. Inspect intake manifold for leaks.

**Sticky Throttle**

**Improper throttle cable used.**
Replace cable.

**Kinked or sharply bent throttle cable.**
Reroute cable to eliminate kinks, sharp bends.

**AeroInjector modified by installer with additional linkages, return springs, brackets, etc.**
Restore AeroInjector to original configuration and install according to this manual.

**Throttle cable lining melted from excessive heat.**
Replace cable. Route cable clear of exhaust system.

**Dirty throttle Slide.**
If the AeroInjector ingests exhaust gases, oil fumes (saturated air filter, etc.), or other materials, they can coat the throttle slide and cause binding. Clean the slide and injector body.

**Sticky Mixture Cable**

**Kinked or sharply bent mixture cable.**
Reroute cable to eliminate kinks, sharp bends.

**Unsupported length of mixture cable too long near AeroInjector mixture lever.**
Install mixture cable as shown in this manual.

**AeroInjector modified by installer with additional linkages, brackets, etc.**
Restore AeroInjector to original configuration and install according to this manual.

**Mixture cable lining melted from excessive heat.**
Replace cable. Route cable clear of exhaust system.

**Fuel Leaks from AeroInjector**

*Because of the AeroInjector's floatless design, fuel will drip/flow from the AeroInjector if the fuel is on. The flow will increase if the throttle is open, the cockpit mixture control is moved towards "Rich", or a fuel pump is on. This is normal and does not represent a defect.*

To keep fuel from flowing from the AeroInjector when the engine is turned off, always keep the fuel shut-off valve turned off, the cockpit mixture control pulled out to "Idle Cut-off", the fuel pump off, and the throttle at "Idle". Always use one of the start-up/shut-down checklists in this manual to prevent fuel from running from the AeroInjector.

**Fuel leak from Mixture Control Valve**

Remove mixture control valve, replace O-Ring and lubricate it with fuel-proof valve seal.
MAINTENANCE

Simplicity of design, combined with a proper installation, result in the AeroInjector requiring no routine or preventive maintenance, year after year.

If you are experiencing a problem with your AeroInjector, refer to the Troubleshooting section of this manual.

The following common topics arise concerning the operation, assembly, and disassembly of the AeroInjector.

Body Assembly and Disassembly
Only six (6) screws and MS nuts hold the AeroInjector together. There is no specific torque value, nor tightening sequence.

The 6 screws that secure the AeroInjector’s body can be removed / installed with a 9/64” hex wrench and a 7/32” box wrench.

O-Rings
The spigot (or flange) is sealed against the cover plate with a reusable Viton O-ring (part no. ACV-Z01-50) installed in a groove in the mating surface of the spigot or flange. This O-ring can be expected to last the lifetime of the AeroInjector.

The spigot (or flange) has a Viton O-ring that can be expected to last the life of the AeroInjector. If replacement should become necessary, see parts list for correct replacement part.

Gaskets and Sealants
There are no sealants or gaskets used anywhere in the AeroInjector.

The AeroInjector is assembled without gaskets or sealants. The thin, black, anti-friction delrin gasket (arrow) is not a sealing gasket.

Delrin Anti-Friction Gasket
The black, anti-friction delrin gasket (see photo, above) is often believed to be a sealing gasket but it is not. Its purpose is to reduce the sliding friction of the throttle slide. It can be expected to last the lifetime of the AeroInjector unless it is warped from excessive heat (improper installation), or severely scratched by debris entering the AeroInjector.

Throttle Slide Lubrication
The throttle slide should never require lubrication. If it binds, identify and correct the cause. Under no circumstances should any lubricant other than a light spray lubricant be applied, and this should never be necessary.

Throttle Slide Cleaning
If an AeroInjector is exposed to oily intake air (leaking engine, oil-soaked air cleaner) or is able to ingest exhaust gasses (exhaust leaks, improper exhaust system) the throttle slide can become covered with a black, sticky residue. This must be removed with solvents and the cause identified and corrected.
Fuel Passage Cleaning
Debris in the fuel passages (from improper fuel filtering) is easily removed, often without removing the AeroInjector from the aircraft.

The main fuel passage (right) can be cleaned by removing the fuel shut-off valve and the fuel line. Clear the passage with compressed air or by flushing with mineral spirits.

The fuel passage for the tapered mixture needle can be cleaned by removing both the needle carrier from the throttle slide and the small plug from the end of the AeroInjector (right). Clear the passage with compressed air or by flushing with mineral spirits.

Removing this plug exposes the metered fuel passage.
Mixture Needles, Key 9:

<table>
